

Stop deciding your stack from year-old blog posts. GrokScope asks **Grok 4.5** (with its native **X search tool**) what developers are saying **this week** — and every claim comes back cited to real X posts, as clickable links with recency tags.

```
$ grokscope ask "bun vs node in 2026"
```

What Developers Are Saying

Users report real gains switching: one developer said moving from Node to Bun "was a game changer... cut process usage across all my services by over 20%" [1]. Colin (Zod creator, now building Nub) put it bluntly: "unless you're using the Bun runtime on your production servers, you shouldn't be using it in dev, and virtually everyone still deploys to Node." [2]

Community Verdict: Node remains the safe default for production and large teams; Bun is preferred for greenfield, CLIs, and anything where startup time and pure DX dominate.

THREE COMMANDS

```
$ grokscope ask "html in production?"
```

→ 30-day research, ≥3 cited posts,
ends with a Community Verdict

```
$ grokscope compare react solidjs
```

→ pros/cons per side from real posts,
winner with caveats

```
$ grokscope trending --topics "rust,go,zig"
```

→ sentiment + top concern + momentum,
one paragraph per topic

USE-CASE IDEAS

- ▶ **Stack decisions** — sanity-check a framework choice against this week's sentiment before committing.
- ▶ **Newsletter & content research** — `trending` is a ready-made "state of X" section with sources.
- ▶ **DevRel monitoring** — `ask "our-sdk pain points" --days 7` in CI, piped to Slack.
- ▶ **Migration timing** — watch momentum turn before you jump (or don't).

WHY IT'S DIFFERENT

- ▶ **Live, not indexed** — Grok 4.5's server-side `x_search` reads X in real time; no stale SEO content.
- ▶ **Every claim cited** — inline numbered citations, rendered as clickable terminal hyperlinks (OSC 8).
- ▶ **Recency tags** — post dates decoded from X snowflake IDs: you see *(4d ago)*, not "recently".
- ▶ **Filters & automation** — `--handles`, `--exclude`, `--days`; `--json` for CI, `--md` for newsletters, `doctor` for setup checks.
- ▶ **BYOK = private** — your xAI key, your data; the cost is printed after every query (~\$0.15–\$0.30, since `x_search` pulls dozens of real posts into context).

SETUP IN 2 MINUTES

- 1 Grab an API key at **console.x.ai** and **add credits** — a new team starts with none (~\$0.15–\$0.30 a query).
- 2 `export GROK_API_KEY=xai-...`
- 3 `npm install -g grokscope` — done. Works on macOS, Linux, Windows (Node ≥ 22).
